	<b>Index</b>	<b>11</b>

A python library for managing a hosts file.

### 1.1 Installation

*Using pip package manager*

```
$ pip install python-hosts
```

*From source*

```
$ git clone https://github.com/jonhadfield/python-hosts
$ cd python-hosts
$ python setup.py install
```

### 1.2 Usage

**Create an instance of a hosts file:**

```
from python_hosts import Hosts, HostsEntry
my_hosts = Hosts()
```

**Add an entry:**

```
new_entry = HostsEntry(entry_type='ipv4', address='1.2.3.4', names=['example.com',
↪ 'example'])
my_hosts.add([new_entry])
```

**Remove an entry/entries matching an address:**

```
my_hosts.remove_all_matching(address='1.2.3.4')
```

**Remove an entry/entries matching an address:**

```
my_hosts.remove_all_matching(name='example.com')
```

**Write entries:**

```
my_hosts.write()
```

## 2.1 Package

This package contains all of the modules utilised by the python-hosts library.

hosts: Contains the Hosts and HostsEntry classes that represent instances of a hosts file and it's individual lines/entries

utils: Contains helper functions to check the available operations on a hosts file and the validity of a hosts file entry

exception: Contains the custom exceptions that are raised in the event of an error in processing a hosts file and its entries

### 2.1.1 Submodules

#### python\_hosts.hosts module

This module contains classes: HostsEntry: A representation of a hosts file entry, i.e. a line containing an IP address and name(s), a comment, or a blank line/line separator.

Hosts: A representation of a hosts file, e.g. /etc/hosts and c:\windows\system32\drivers\etc\hosts for a linux or MS windows based machine respectively. Each entry being represented as an instance of the HostsEntry class.

**class** `python_hosts.hosts.Hosts` (*path=None*)

Bases: `object`

A hosts file.

**add** (*entries=None, force=False, allow\_address\_duplication=False, merge\_names=False*)

Add instances of HostsEntry to the instance of Hosts. :param entries: A list of instances of HostsEntry :param force: Remove matching before adding :param allow\_address\_duplication: Allow using multiple entries for same address :param merge\_names: Merge names where address already exists :return: The counts of successes and failures

**count** ()

Get a count of the number of host entries :return: The number of host entries

**static determine\_hosts\_path** (*platform=None*)

Return the hosts file path based on the supplied or detected platform. :param platform: a string used to identify the platform :return: detected filesystem path of the hosts file

**entries**

**exists** (*address=None, names=None, comment=None*)

Determine if the supplied address and/or names, or comment, exists in a HostsEntry within Hosts :param address: An ipv4 or ipv6 address to search for :param names: A list of names to search for :param comment: A comment to search for :return: True if a supplied address, name, or comment is found. Otherwise, False.

**find\_all\_matching** (*address=None, name=None*)

Return all HostsEntry instances from the Hosts object where the supplied ip address or name matches :param address: An ipv4 or ipv6 address :param name: A host name :return: HostEntry instances

**static get\_hosts\_by\_url** (*url=None*)

Request the content of a URL and return the response :param url: The URL of the hosts file to download :return: The content of the passed URL

**hosts\_path**

**import\_file** (*import\_file\_path=None*)

Read a list of host entries from a file, convert them into instances of HostsEntry and then append to the list of entries in Hosts :param import\_file\_path: The path to the file containing the host entries :return: Counts reflecting the attempted additions

**import\_url** (*url=None, force=None*)

Read a list of host entries from a URL, convert them into instances of HostsEntry and then append to the list of entries in Hosts :param url: The URL of where to download a hosts file :return: Counts reflecting the attempted additions

**populate\_entries** ()

Called by the initialiser of Hosts. This reads the entries from the local hosts file, converts them into instances of HostsEntry and adds them to the Hosts list of entries. :return: None

**remove\_all\_matching** (*address=None, name=None*)

Remove all HostsEntry instances from the Hosts object where the supplied ip address or name matches :param address: An ipv4 or ipv6 address :param name: A host name :return: None

**write** (*path=None*)

Write all of the HostsEntry instances back to the hosts file :param path: override the write path :return: Dictionary containing counts

**class** python\_hosts.hosts.**HostsEntry** (*entry\_type=None, address=None, comment=None, names=None*)

Bases: object

An entry in a hosts file.

**address**

**comment**

**entry\_type**

**static get\_entry\_type** (*hosts\_entry=None*)

Return the type of entry for the line of hosts file passed :param hosts\_entry: A line from the hosts file :return: 'comment' | 'blank' | 'ipv4' | 'ipv6'

**is\_real\_entry** ()

**names**

**static str\_to\_hostentry** (*entry*)

Transform a line from a hosts file into an instance of HostsEntry :param entry: A line from the hosts file  
:return: An instance of HostsEntry

## python\_hosts.utils module

This module contains utility functions used by the Hosts and HostsEntry methods

`python_hosts.utils.dedupe_list` (*seq*)

Utility function to remove duplicates from a list :param seq: The sequence (list) to deduplicate :return: A list with original duplicates removed

`python_hosts.utils.is_ipv4` (*entry*)

Check if the string provided is a valid ipv4 address :param entry: A string representation of an IP address :return: True if valid, False if invalid

`python_hosts.utils.is_ipv6` (*entry*)

Check if the string provided is a valid ipv6 address :param entry: A string representation of an IP address :return: True if valid, False if invalid

`python_hosts.utils.is_readable` (*path=None*)

Test if the supplied filesystem path can be read :param path: A filesystem path :return: True if the path is a file that can be read. Otherwise, False

`python_hosts.utils.valid_hostnames` (*hostname\_list*)

Check if the supplied list of strings are valid hostnames :param hostname\_list: A list of strings :return: True if the strings are valid hostnames, False if not

## python\_hosts.exception module

### hosts.exceptions

All exceptions used in the hosts code base are defined here.

**exception** `python_hosts.exception.HostsEntryException`

Bases: `exceptions.Exception`

Base exception class. All HostsEntry-specific exceptions should subclass this class.

**exception** `python_hosts.exception.HostsException`

Bases: `exceptions.Exception`

Base exception class. All Hosts-specific exceptions should subclass this class.

**exception** `python_hosts.exception.InvalidComment`

Bases: `python_hosts.exception.HostsEntryException`

Raised when a HostsEntry is defined as type 'comment' but with an invalid comment

**exception** `python_hosts.exception.InvalidIPv4Address`

Bases: `python_hosts.exception.HostsEntryException`

Raised when a HostsEntry is defined as type 'ipv4' but with an invalid address.

**exception** `python_hosts.exception.InvalidIPv6Address`

Bases: `python_hosts.exception.HostsEntryException`

Raised when a HostsEntry is defined as type 'ipv6' but with an invalid address.

**exception** `python_hosts.exception.UnableToWriteHosts`

Bases: `python_hosts.exception.HostsException`

Raised when a Hosts file cannot be written.
